(a) 32 cells enter, none meets the definition

32 screened cells
6 datasets, 3 backbones

1. worth preserving?
7 of 31 clear $V_{ridge} \geq 0.20$

measured against a baseline fit on the cell's own data

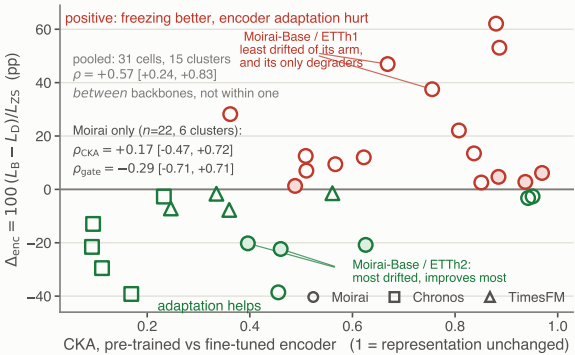
2. representation changed?
CKA, measured on all 31

a measurement, not a filter: every cell continues, and no help out of sample

3. did adaptation matter?
fine-tune (B) vs freeze (D)

held-out windows, not the selection windows: 4 of 31 reverse sign

4. capability destroyed?
0 cells meet all 3 clauses

4 of the 7 survivors are 8–42% better fine-tuned


(b) no cut on CKA separates them (best misplaces 5)
